

Abstract of Disclosure

[0052] A skid has a pair of laterally disposed base members and a first and a second support member for mounting a first and second piece of equipment requiring horizontal axial alignment, for example, a pump and a motor. At least one of the first and second support members is releaseably and adjustably vertically attachable to and between the pair of base members. For example, the first support member is a pair of cross members, wherein each of the cross members is attached at their ends substantially perpendicular to the base members forming a right parallelogram. Further, in this example, the second support member is vertically positioned relative to the base members such that a set of holes in each of the second support member and the pair of base members are horizontally aligned and fasteners are used to secure the two to each other in that position.
